Citation: Philippe Sainty (2023) About the strong EULER-GOLDBACH conjecture. J. Math. Stat. Anal. 5: 101

#### Abstract

In this paper, a "local" algorithm is determined for the construction of two recurrent sequences of positive primes $\left(U_{2 n}\right)$ and $\left(V_{2 n}\right),\left(\left(U_{2 n}\right)\right.$ dependent on $\left.\left(V_{2 n}\right)\right)$, such that for each integer $\mathrm{n} \geq 2$, their sum is equal to 2 n . To form this, a third sequence of primes $\left(W_{2 n}\right)$ is defined for any integer $n \geq 3$ by: $W_{2 n}=\operatorname{Sup}(\mathrm{p} \in \mathcal{P}: \mathrm{p} \leq 2 n-3)$, where $\mathcal{P}$ is the infinite set of primes. Goldbach's conjecture has been proved for all even integers $2 n$ between 4 and $4.10^{18}$. In the table of terms of Goldbach sequences given in appendix 10 , values of the order of $2 \mathrm{n}=10^{1000}$ are reached.This "ascent and descent " algorithm proves Goldbach's conjecture ; an analogous proof by recurrence is established and an increase of $U_{2 n}$ by $0.7(\ln (2 n))^{2.2}$ is established. Moreover, the Lagrange-Lemoine-Levy conjecture and its generalization, the Bezout-Goldbach conjecture, are proven by the same type of procedure.

Keywords: Prime numbers, prime number theorem, weak and strong Goldbach conjectures, Bertrand-Chebyshev theorem, gaps between consecutive primes, Lagrange-Lemoine-Levy conjecture, Bezout-Goldbach conjecture.

## 1 Background

Number theory, "the queen of mathematics" deals with structures and properties defined on integers and primes (see Euclid [11], Hadamard [13], Hardy \& Wright [14], Landau [20]). Numerous problems have been raised and conjectures made, the statements of which are often simple but very dificult to prove. These main components include:

## Elementary arithmetic

* Determination and properties of primes.
* Operations on integers (basic operations, congruence, gcd, lcm, $\qquad$ .).
* Decomposition of integers into products or sums of primes (fundamental theorem of arithmetic, decomposition of large numbers, cryptography, and Goldbach's conjecture) .

## Analytical number theory :

* The Riemann hypothesis.
* Distribution of primes (Prime number theorem, Hadamard [13], De la Vallée-Poussin [33], Littlewood [23] and Erdos [10] ).
* Gaps between consecutive primes, (Bombieri \& Davenport, [3], Cramer [8], Baker, Harmann, Iwaniec \& Pintz [4], [5],[18], Granville [12], Shanks [27], Tchebychev [32] and Zhang [36]).

Algebraic, probabilistic, combinatorial and algorithmic number theories.

* Modular arithmetic, diophantine approximations, equations.
* Arithmetic functions and algebraic geometry.

## 2 Definitions, notations and reminders

(2.1) The integers $n, k, p, q, r$, $\qquad$ are always positive.
(2.2) Let $\mathcal{P}$ the infinite set of positive primes (called simply primes) :

$$
\begin{aligned}
& \mathcal{P}=\left\{p_{k}\left(\mathrm{k} \in \mathrm{IN}^{*}\right): \mathrm{p}_{\mathrm{k}} \text { is the kth positive prime } ;\left(\mathrm{p}_{\mathrm{k}}<\mathrm{p}_{\mathrm{k}+1} \text { and } \lim p_{k}=+\infty\right)\right\} \\
& \qquad\left(p_{1}=2 ; p_{2}=3 ; p_{3}=5 ; p_{4}=7 ; p_{5}=11 ; p_{6}=13 ; \ldots \ldots \ldots\right)
\end{aligned}
$$

(2.3) The writing of large numbers (see appendix 10 ) is simplified using the following constants :
a) $\mathrm{M}=10^{9}$
b) $\mathrm{R}=4.10^{18}$
c) $\mathrm{G}=10^{100}$
d) $\mathrm{S}=10^{500}$
e) $\mathrm{T}=10^{1000}$
(2.4) $\ln (x)$ denotes the neperian logarithm of the strictly positive real $x,(x>0)$.
(2.5) Let $\left(W_{2 n}\right)$ be the sequence of primes defined by:
(2.5.1) For any integer $\mathrm{n} \geq 3$,

$$
W_{2 n}=\operatorname{Sup}(\mathrm{p} \in \mathcal{P}: \mathrm{p} \leq 2 \mathrm{n}-3)
$$

(2.6) Any sequence denoted by $\left(G_{2 n}\right)=\left(U_{2 n} ; V_{2 n}\right)$ verifying the property:
"For any integer $\mathrm{n} \geq 2, U_{2 n}$ and $V_{2 n}$ are primes and $U_{2 n}+V_{2 n}=2 \mathrm{n}$ ", is called a Goldbach sequence.
(2.7) Iwaniec \& Pintz [18] have shown that for any integer $n \in \mathbb{N}+3$, there is always a prime between $n-n^{23 / 42}$ and $n$.

Baker \& Harman [4], [5] concluded that for any sufficiently large integer $n$ there is a prime in the interval [ $\left.n ; n+o\left(n^{0.525}\right)\right]$. Thus this results provides an increase of the gap between two consecutive primes $p_{k}$ and $p_{k+1}$ of the form :
(2.7.1) $\forall \varepsilon>0, \exists k_{\varepsilon} \in \mathbb{N}^{*} / \forall \mathrm{k} \in \mathbb{N}^{*},\left(\mathrm{k}>k_{\varepsilon}\right), \quad \quad p_{k+1}-p_{k}<\varepsilon . p_{k}{ }^{0.525}$
(2.8) According to the Cramer-Maier-Nicely conjecture [1], [3], [8], [12], [24], [25], for any real c $>2$, for any integer $\mathrm{k} \geq 500$,

$$
\begin{equation*}
p_{k+1}-p_{k} \leq 0.7\left(\ln \left(p_{k}\right)\right)^{c} \quad(\text { with probability one }) . \tag{2.8.1}
\end{equation*}
$$

## 3 Introduction

Chen [6], Hardy \& Littlewood [15], Hegfollt [16], Ramaré \& Saouter [26], Tao [31], Tchebychev [32] and Vinogradov [34] have taken important steps and obtained promising results on Goldbach's conjecture.
Indeed, Helfgott \& Platt proved Goldbach's weak conjecture in 2013. Silva, Herzog \& Pardi [29] held the record for calculating the terms of Goldbach sequences after determining pairs of primes $\left(U_{2 n} ; V_{2 n}\right)$ verifying :

$$
\begin{equation*}
\text { For any integer } \mathrm{n},\left(4 \leq 2 \mathrm{n} \leq 4.10^{18}\right):\left(U_{2 n}+V_{2 n}=2 \mathrm{n}\right) \tag{3.1}
\end{equation*}
$$

In previous research work, there is no explicit construction of recurrent sequences of Goldbach primes of the form :

$$
\left(G_{2 n}\right)=\left(U_{2 n} ; V_{2 n}\right) \text { satisfying for any integer } \mathrm{n} \geq 2 \text { the equality : }\left(U_{2 n}+V_{2 n}=2 \mathrm{n}\right)
$$

In this article, two sequences of primes are developed using a simple and efficient algorithm to compute for any integer $\mathrm{n} \geq 3$ by successive iterations any term $U_{2 n}^{2 \mathrm{n}}$ and $V_{2 n}^{2 \mathrm{n}}$ of a Goldbach sequence. Using Maxima scientific software on a personal computer, Silva's record is broken, and the values $2 \mathrm{n}=10^{500}$ and even $2 \mathrm{n}=10^{1000}$ are reached. The proof of Goldbach's conjecture can be established on the same principle, using reasoning by recurrence. Moreover, the Lagrange-Lemoine-Lévy conjectures [9], [17], [19], [24], [25], [30], [35] and its generalization, the Bezout-Goldbach conjecture are validated. Using case disjunction reasoning, we construct two recurrent sequences of primes $\left(V_{2 n}\right)$ and $\left(U_{2 n}\right)$ according to the sequence $\left(\mathrm{W}_{2 \mathrm{n}}\right)$ by the following process. For any integer $\mathrm{n} \geq 2$,

$$
\begin{equation*}
\left(U_{4}=2 ; V_{4}=2\right) \tag{3.2}
\end{equation*}
$$

Let n be an integer, $(\mathrm{n} \geq 3)$ :
1.Either, $\left(2 \mathrm{n}-W_{2 n}\right)$ is a prime, then $U_{2 n}$ and $V_{2 n}$ are defined directly in terms of $W_{2 n}$.
$\underline{\text { 2. Either, }}\left(2 \mathrm{n}-W_{2 n}\right)$ is a composite number, then $V_{2 n}$ and $U_{2 n}$ are defined from the preceding terms of the sequence $\left(G_{2 n}\right)$.

## 4 Methodology

To determine pairs of primes that verify Goldbach's conjecture, three sequences of primes $\left(W_{2 n}\right),\left(\mathrm{V}_{2 n}\right),\left(U_{2 n}\right)$ are defined and verify the following properties :
(4.1) $\lim V_{2 n}=+\infty$.
(4.2) For any integr $\mathrm{n} \geq 2, V_{2 n}$ is defined as a function of $W_{2 n}=\operatorname{Sup}(\mathrm{p} \in \mathrm{P}: \mathrm{p} \leq 2 \mathrm{n}-3)$.
(4.3) $\left(W_{2 n}\right)$ is an increasing sequence that contains all primes except $p_{1}=2$.
(4.4) $\lim W_{2 n}=+\infty$.
(4.5) $\left(U_{2 n}\right)$ is a complementary sequence of negligible primes with respect to $2 \mathrm{n},\left(U_{2 n} \ll 2 \mathrm{n}\right)$.
(4.6) For any integer $n \geq 3$,

If $\left(2 \mathrm{n}-W_{2 n}\right)$ is a prime " special case ", then $V_{2 n}$ and $U_{2 n}$ are defined by :

$$
\begin{equation*}
V_{2 n}=W_{2 n} \text { and } U_{2 n}=2 \mathrm{n}-W_{2 n} \tag{4.7}
\end{equation*}
$$

Otherwise, if ( $2 \mathrm{n}-W_{2 n}$ ) is a composite number " general case ",
we use the previous terms of the sequence $\left(G_{2 n}\right)$. So we look for an integer k to obtain two terms $U_{2(n-k)}$ and $V_{2(n-k)}$ satisfying the following conditions :

$$
\begin{align*}
& U_{2(n-k)}, \quad V_{2\left(n^{-} k\right)} \text { and } U_{2(n-k)}+2 \mathrm{k} \text { are primes } U_{2(n-k)}+V_{2\left(n^{-} k\right)}=2(\mathrm{n}-\mathrm{k})  \tag{4.8}\\
& \text { (which is always possible ; see the proof in Theorem 5). }
\end{align*}
$$

Thus, by setting :

$$
\begin{equation*}
V_{2 n}=V_{2(n-k)} \text { and } U_{2 n}=U_{2(n-k)}+2 \mathrm{k} \tag{4.9}
\end{equation*}
$$

two new primes $V_{2 n}$ and $U_{2 n}$ satisfying (4.10) are generated.

$$
\begin{equation*}
U_{2 n}+V_{2 n}=2 \mathrm{n} \tag{4.10}
\end{equation*}
$$

This process is then repeated, incrementing $n$ by one unit : $n \rightarrow n+1$ ).

## 5 Theorem

There exists a recurrent Goldbach sequence of primes $\left(G_{2 n}\right)=\left(U_{2 n} ; V_{2 n}\right)$ satisfying for any integer $\mathrm{n} \geq 2$ :

$$
U_{2 n} \text { and } V_{2 n} \text { are primes and their sum is equal to } 2 \mathrm{n} \text {. }
$$

$$
\begin{equation*}
\left(\mathrm{U}_{2 n}, V_{2 n} \in \mathcal{P} \quad \text { and } U_{2 n}+V_{2 n}=2 \mathrm{n}\right) . \tag{5.1}
\end{equation*}
$$

An algorithm can be used to explicitly compute any term $U_{2 n}$ and $V_{2 n}$.

## Proof of Theorem 5

## First Method :

For any integer $\mathrm{n} \geq 3$,
If $\left(2 \mathrm{n}-W_{2 n}\right)$ is a prime, then $V_{2 n}$ and $U_{2 n}$ are defined by:

$$
\begin{equation*}
V_{2 n}=W_{2 n} \quad \text { and } \quad U_{2 n}=2 \mathrm{n}-W_{2 n} \tag{5.3}
\end{equation*}
$$

Otherwise,
if $\left(2 \mathrm{n}-W_{2 n}\right)$ is a composite number,
we use the previous terms of the sequence $\left(G_{2 n}\right)$ to determine $\left(U_{2 n}\right)$ and $\left(V_{2 n}\right)$.
For any integer $q$ such that: $(1 \leq \mathrm{q} \leq \mathrm{n}-3)$, we have : $3 \leq U_{2(n-q)} \leq \mathrm{n}$.
For any integer k such that $(4 \leq 2 \mathrm{k} \leq \mathrm{n}-1)$, there are two primes $p_{m}$ and $p_{r},(\mathrm{~m}>\mathrm{r})$ in the interval $[4 ; n]$ such that :

$$
\begin{equation*}
p_{m}-p_{r}=2 \mathrm{k} \tag{5.4}
\end{equation*}
$$

(see Bombieri \& Davenport [1], Cramer [8], Iwaniec \& Pintz [18] , Tchebychev [32]).
Then there is an integer $k$ verifying, $(4 \leq 2 \mathrm{k} \leq \mathrm{n}-3)$ such that:

$$
\begin{equation*}
R_{2 n}=U_{2(n-k)}+2 \mathrm{k} \text { is a prime } \tag{5.5}
\end{equation*}
$$

The smallest integer k denoted $k_{n}$ such that $R_{2 n}$ is a prime is chosen. So let :

$$
\begin{align*}
& U_{2 n}=U_{2\left(n-k_{n}\right)}+2 k_{n} \text { and } \mathrm{V}_{2 \mathrm{n}}=V_{2\left(n-k_{n}\right)}  \tag{5.6}\\
& \text { (These two terms are primes) }
\end{align*}
$$

In the previous steps two primes, $U_{2\left(n-k_{n}\right)}$ and $V_{2\left(n-k_{n}\right)}$ whose sum is equal to $2\left(\mathrm{n}-\boldsymbol{k}_{n}\right)$ were determine

$$
\begin{equation*}
U_{2\left(n-k_{n}\right)}+V_{2\left(n-k_{n}\right)}=2\left(\mathrm{n}-k_{n}\right) \tag{5.7}
\end{equation*}
$$

By adding the term $k_{n}$ to each member of the equality (5.6), it follows :

$$
\begin{array}{ll} 
& U_{2\left(n-k_{n}\right)}+2 k_{n}+V_{2\left(n-k_{n}\right)}=2\left(\mathrm{n}-k_{n}\right)+2 k_{n} \\
\Leftrightarrow & \left\{U_{2\left(n-k_{n}\right)}+2 k_{n}\right\}+V_{2\left(n-k_{n}\right)}=2 \mathrm{n} \\
\Leftrightarrow & U_{2 n}+V_{2 \mathrm{n}}=2 \mathrm{n} \tag{5.10}
\end{array}
$$

Finally, for any integer $\mathrm{n} \geq 3$, this algorithm determines two sequences of primes $\left(U_{2 \mathrm{n}}\right)$ and $\left(V_{2 \mathrm{n}}\right)$ verifying Goldbach's conjecture.

## Second Method :

The demonstration can be made using the following strong recurrence principle.
Let $\mathrm{P}(\mathrm{n})$ be the following property defined for any integer $\mathrm{n} \geq 2$ by :
$\mathrm{P}(\mathrm{n})$ : "For any integer p satisfying: $(2 \leq \mathrm{p} \leq \mathrm{n})$, there exists two primes $U_{2 p}$ and $V_{2 p}$ and such their sum is

$$
\text { equal to } 2 \mathrm{p}:\left(U_{2 p}+V_{2 p}=2 \mathrm{p}\right) "
$$

Let us show by strong recurrence that $\mathrm{P}(\mathrm{n})$ is true for any integer $\mathrm{n} \geq 2$.
a) $\mathrm{P}(2)$ is true : it suffices to choose $U_{4}=V_{4}=2$.
b) Let us show that the property $\mathrm{P}(\mathrm{n})$ is hereditary: (i.e for any integer $\mathrm{n} \geq 2 \mathrm{P}(\mathrm{n}) \Rightarrow P(\mathrm{n}+1)$ )

Assume property $\mathrm{P}(\mathrm{n})$ is true,
If $\left(2\left(\mathrm{n}+1-W_{2(n+1)}\right)\right.$ is a prime, then $V_{2(n+1)}$ and $U_{2(n+1)}$ are defined by :

$$
\begin{equation*}
V_{2}\left(n^{+}{ }_{1}\right)=W_{2}\left(n^{+}{ }_{1}\right) \quad \text { and } \quad U_{2}\left(n^{+}{ }_{1}\right)=2(\mathrm{n}+1)-W_{2}\left(n^{+}{ }_{1}\right) \tag{5.11}
\end{equation*}
$$

Otherwise, if $\left(2(\mathrm{n}+1)-W_{2(n+1)}\right)$ is a composite number,
there exists an integer k to obtain two terms $U_{2(n+1-k)}$ and $V_{2(n+1-k)}$ satisfying the following conditions :

$$
\begin{align*}
& U_{2(n+1-k)}, V_{2(n+1-k)} \text { and } U_{2(n+1-k)}+2 \mathrm{k} \text { are primes. }  \tag{5.12}\\
& U_{2(n+1-k)}+V_{2(n+1-k)}=2(\mathrm{n}+1-\mathrm{k}) \quad(\text { which is always possible } ; \text { see first method }) .
\end{align*}
$$

Thus, by setting :

$$
\begin{equation*}
V_{2(n+1)}=V_{2(n+1-k)} \quad \text { and } U_{2(n+1)}=U_{2(n+1-k)}+2 \mathrm{k} \tag{5.13}
\end{equation*}
$$

two new primes $V_{2(n+1)}$ and $U_{2(n+1)}$ satisfying $\left.U_{2(n+1)}+V_{2(n+1)}=2(\mathrm{n}+1)\right)$ are generated. It follows that $\mathrm{P}(\mathrm{n}+1)$ is true, then the property $\mathrm{P}(\mathrm{n})$ is hereditary : $(\mathrm{P}(\mathrm{n})=>\mathrm{P}(\mathrm{n}+1))$.

Therefore, for any integer $\mathrm{n} \geq 2$ the property $\mathrm{P}(\mathrm{n})$ is true ; it follows that :
$\forall \mathrm{n} \geq 2$ there are two primes $U_{2 n}$ and $V_{2 n}$ and such their sum is $2 \mathrm{n}:\left(U_{2 n}+V_{2 n}=2 \mathrm{n}\right)$

## 6 Lemma

The sequence $\left(U_{2 n}\right)$ verifies the following estimation : For any integer $\mathrm{n} \geq 65$,

$$
\begin{equation*}
U_{2 n} \leq(2 n)^{0.55} \tag{6.1}
\end{equation*}
$$

## Proof of Lemma 6

According to the programm 9.2 and appendix 10, the estimate (6.1) is verified for any integer n such that : ( $65 \leq \mathrm{n} \leq 2000$ )
.For any integer $\mathrm{n}>2000$, the proof is established by recurrence. For this purpose, let $P_{1}(\mathrm{n})$ be the following property :
(6.2) $P_{1}(\mathrm{n})$ : " There exists a strictly increasing sequence of positive numbers $\left(C_{n}\right)$ such that : $U_{2 n} \leq C_{n}(2 n)^{0.525}$ ".
a) $P_{1}(2000)$ is true according to program 9.2 and the table in appendix 10 .
b) For any integer $\mathrm{n} \geq 2000$, let us show that $P_{1}(\mathrm{n})$ is hereditary, (i.e $P_{1}(\mathrm{n}) \Rightarrow P_{1}(\mathrm{n}+1)$ )

Assume that $P_{1}(\mathrm{n})$ is true : then,
If ( $\left.2(\mathrm{n}+1)-W_{2(n+1)}\right)$ is a prime, then $V_{2(n+1)}$ and $U_{2(n+1)}$ are defined by :

$$
\begin{equation*}
V_{2}\left(n^{+}{ }_{1}\right)=W_{2}\left(n^{+}{ }_{1}\right) \quad \text { and } \quad U_{2}\left(n^{+}{ }_{1}\right)=2(\mathrm{n}+1)-W_{2}\left(n^{+}{ }_{1}\right) \tag{6.3}
\end{equation*}
$$

According to the results in [4], [5], [18] there is a constant $\mathrm{K},(0<\mathrm{K}<1) /$

$$
2(\mathrm{n}+1)-\mathrm{K}(2(n+1))^{0.525}<W_{2(n+1)}<2(\mathrm{n}+1)
$$

$$
\Rightarrow \quad U_{2(n+1)}<\mathrm{K}(2(n+1))^{0.525}
$$

$$
\Rightarrow \quad U_{2(n+1)} \leq C_{n+1}(2(n+1))^{0.525}
$$

Otherwise, if $\left(2(\mathrm{n}+1)-W_{2(n+1)}\right)$ is a composite number,

$$
\begin{array}{cc} 
& \exists \mathrm{p} \in \mathbb{N}^{*} / U_{2(n+1)}=U_{2(n+1-p)}+2 \mathrm{p}  \tag{6.4}\\
U & <
\end{array}
$$

According to [4], [5], [18], the smallest integer $p$ defined in (6.4) verifies:

$$
\begin{equation*}
2 \mathrm{p}<\mathrm{K} U_{2(n+1-p)}^{0.525} \tag{6.5}
\end{equation*}
$$

and

$$
U_{2(n+1-p)}<C_{n+1-p}(2(n+1-p))^{0.525}
$$

It follows :

$$
U_{2(n+1)}<\mathrm{K} C_{n+1-p}^{0.525}(2(n+1-p))^{0.275625}+C_{n+1-p}(2(n+1-p))^{0.525}
$$

Then,
(6.6)

$$
U_{2(n+1)}<C_{n+1} \cdot(2(n+1))^{0.525}
$$

and, by setting: $C_{n}=(2 n)^{0.025}$, it follows :

$$
\begin{equation*}
U_{2(n+1)}<(2(n+1))^{0.55} \tag{6.7}
\end{equation*}
$$

$P_{1}(\mathrm{n}+1)$ is true then $P_{1}(\mathrm{n})$ is hereditary. So for any integer $\mathrm{n} \geq 2000$, the property $P_{1}(\mathrm{n})$ is true.
(The inequality (6.7) is verified with the aid of the scientific software Maple studying the functions of the type :

$$
\left.\mathrm{f}: \mathrm{x} \rightarrow \mathrm{a} x^{0.275625}+\mathrm{b} x^{0.525} \text { increased by } \mathrm{g}: \mathrm{x} \rightarrow x^{0.55},(\mathrm{a}, \mathrm{~b}>0)\right)
$$

* Remark : A more precise mark-up can be obtained using the Cippola or Axler frames. [7], [2].

## 7 Theorem

For any integer $\mathrm{n} \geq 3$, it is easy to check :
$7.1\left(W_{2 n}\right)$ is a positive increasing sequence of primes.
$7.2\left\{W_{2 n}: \mathrm{n} \in \mathrm{IN}^{*}\right\} \cup\{2\}=\mathcal{P}$
$7.3 \lim W_{2 n}=+\infty$
$7.4\left(V_{2 n}\right)$ is a sequence of primes.
The following results are validated with probability one:
$7.5 \mathrm{n} \leq V_{2 n} \leq W_{2 n}$
$7.63 \leq 2 n-W_{2 n} \leq U_{2 n} \leq \mathrm{n}$
$7.7 \lim V_{2 n}=+00$

## Proof of Theorem 7

7.1 For any integer $\mathrm{n} \geq 2$ let $A_{n}$ be the following set: $A_{n}=\left\{p_{k} \in \mathcal{P}: p_{k} \leq 2 \mathrm{n}-3\right\}$.
$A_{n} \subset A_{n+1}$ therefore, $W_{2 n} \leq W_{2(n+1)}$, so the sequence $\left(W_{2 n}\right)$ is a positive increasing sequence of primes.
7.2 Any prime except $p_{1}=2$ is odd, hence the result.
$7.3 \lim W_{2 n}=\lim p_{n}=+o o$.
7.4 By definition $V_{2 n}=W_{2 n}$ or there exits an integer $\mathrm{k} \leq \mathrm{n}-2$ such that: $V_{2 n}=V_{2(n-k)}$; so, by reccurence the terms of the sequence $\left(V_{2 n}\right)$ are primes ; moreover, there exists a strictly increasing sub-sequence $\left(V_{2 n}^{\prime}\right)$ of $\left(V_{2 n}\right)$ verifying $\lim \left(V_{2 n}^{\prime}\right)=+$ oo.
7.5 According to Lemma 6 , for any integer $\mathrm{n} \geq 65, U_{2 n}<(2 n)^{0.55}$; therefore,

$$
U_{2 n}<(2 n)^{0.55}<\mathrm{n} \quad \text { and } \quad V_{2 n}=2 \mathrm{n}-U_{2 n}>2 \mathrm{n}-\mathrm{n}>\mathrm{n} .
$$

For any integer $\mathrm{n} /(3 \leq \mathrm{n} \leq 65)$, verification is carried out according to the program in 9.2 and the table in appendix 10 .
7.6 According to 7.5,

$$
\begin{gathered}
\mathrm{n} \leq V_{2 n} \Rightarrow U_{2 n}=2 \mathrm{n}-V_{2 n} \leq 2 \mathrm{n}-\mathrm{n} \leq \mathrm{n} ; \text { moreover, } \\
V_{2 n} \leq W_{2 n} \Rightarrow 2 \mathrm{n}-W_{2 n} \leq 2 \mathrm{n}-V_{2 n}=U_{2 n} .
\end{gathered}
$$

7.7 By 7.5, for any integer $\mathrm{n} \geq 2, \mathrm{n} \leq V_{2 n}$, so $\lim \left(V_{2 n}\right)=+o o$.

## 8 Remarks

8.1 There are infinitely many integers $n$ such that: $U_{2 n}=3,5,7$ or 11 .
$8.2 V_{2 n} \sim 2 n \quad$ for $(\mathrm{n} \rightarrow+\infty)$.
8.3 For any sufficiently large integer $\mathrm{n},(\mathrm{n} \geq 5000) \mathrm{:}_{2} \quad{ }_{2 n} U_{2 n} \ll V_{2 n} \quad$ and $\quad \lim \left(\mathrm{U}_{2 \mathrm{n}} / \mathrm{V}_{2 \mathrm{n}}\right)=0$.
8.4 The smallest integer n such that : $U_{2 n} \neq 2 \mathrm{n}-W_{2 n}$ is obtained for $\mathrm{n}=49$ and $G_{98}=(79 ; 19)$.
(This type of term increases in the Goldbach sequence $\left(\mathrm{G}_{2 n}\right)$ as n increases, in the sense of the Schnirelmann density, and there are an infinite number of them; their proportion per interval can be computed using the results given in [28]).
8.5 If $\mathrm{q} \geq 5$ is an odd integer, we could generalize this algorithm with sequences $\left(W^{\prime}{ }_{2 n}\right)$ defined by :
(8.6.1) $\quad \forall \mathrm{n} \in \mathbb{N},(\mathrm{n} \geq \mathrm{q}+1.5)$

$$
W^{\prime}{ }_{2 n}=\operatorname{Sup}(\mathrm{p} \in \mathcal{P} \quad: \mathrm{p} \leq 2 \mathrm{n}-\mathrm{q}) .
$$

Other Goldbach sequences $\left(G^{\prime}{ }_{2 n}\right)$ independent of $\left(G_{2 n}\right)$ are thus generated.
8.6 The sequence $\left(G_{2 n}\right)$ is extremal in the sense that for any integer $\mathrm{n} \geq 2, V_{2 n}$ and $U_{2 n}$ are the largest and smallest possible primes such that: $U_{2 n}+V_{2 n}=2 \mathrm{n}$.
8.7 The Cramer-Maier-Nicely conjecture [8], [ 12 ], [17 ], [19], [21], [22], [24], [25], [30] is verified with probability one. It leads to the following mark-up : For any integer $p \geq 500$,

$$
\begin{equation*}
U_{2 p} \leq 0.7(\ln (2 \mathrm{p}))^{(2.2-1 / \mathrm{p})} \quad(\text { with probability one }) \tag{8.7.1}
\end{equation*}
$$

The proof is similar to that of Lemma 6, using the same type of reasoning by recurrence, validated by the study of functions of the type: $\mathrm{f}: \mathrm{x} \rightarrow \mathrm{ag}(\mathrm{x})+\mathrm{b}\left(\ln (\mathrm{g}(\mathrm{x}))^{c}(\mathrm{a}, \mathrm{b}>0),(\mathrm{c}>2)\right.$, ( with $\left.\mathrm{g}: \mathrm{x} \rightarrow 0.7(\ln (x))^{(c-1 / \mathrm{x})}\right)$ and $\mathrm{h}: \mathrm{x} \rightarrow 0.7(\ln (x))^{(2.2-1 / \mathrm{x})}$ using Maple software.

* Remark : A better mark-up can be obtained via [24], [25], [27] .
8.8 According to Bombieri [3] and using the same method as in the proof of Lemma 6 , we obtain the following estimate of $U_{2 n}$ :

$$
\begin{equation*}
\forall \varepsilon>0, \quad U_{2 n}=\mathrm{O}\left((\ln (2 n))^{1.3++^{\varepsilon}}\right), \tag{8.8.1}
\end{equation*}
$$

(on average).

## 9 Algorithm

## Algorithm written in natural language

## Inputs

Input four integer variables : $\mathrm{k}, \mathrm{N}, \mathrm{n}, \mathrm{P}$.
Input : $p_{1}=2, p_{2}=3, p_{3}=5, p_{4}=7, \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots, p_{N}$ the first N primes. :
Input: $\mathrm{n}=3$.
Input : $\mathrm{P}=\mathrm{M}, \mathrm{R}, \mathrm{G}, \mathrm{S}$ or T as indicated in paragraph 2.

## Algorithm body

A) Compute: $W_{2 n}=\operatorname{Sup}(\mathrm{p} \in \mathcal{P}: \mathrm{p} \leq 2 \mathrm{n}-3)$

If $T_{2 n}=\left(2 \mathrm{n}-W_{2 n}\right)$ is a prime,
Let:
(9.1.1) $\quad U_{2 n}=T_{2 n}$ and $V_{2 n}=W_{2 n}$
otherwise ,
B) If $T_{2 n}$ is a composite number, let : $\mathrm{k}=1$.
B.1) While $U_{2(n-k)}+2 \mathrm{k}$ is a composite number,
assign to k the value : $\mathrm{k}+1(\mathrm{k} \rightarrow \mathrm{k}+1)$.
Return to B1)
End While .
Assign to k the value $:\left(\mathrm{k} \rightarrow k_{n}\right)$
(9.1.2) Let:

$$
U_{2 n}=U_{2\left(n-k_{n}\right)}+2 k_{n} \text { and } V_{2 n}=V_{2\left(n-k_{n}\right)}
$$

Assign to n the value $\mathrm{n}+1,(\mathrm{n} \rightarrow n+1)$ and return to A$)$
End :
Outputs for integers less than $10^{4:}: \operatorname{Print}\left(2 \mathrm{n}=\ldots ; 2 \mathrm{n}-3=\ldots ; W_{2 n}=\ldots ; T_{2 n}=\ldots ; V_{2 n}=\ldots ; U_{2 n}=\ldots\right.$ ).
Outputs for large integers : Print ( $2 \mathrm{n}-\mathrm{P}=\ldots ; 2 \mathrm{n}-3-\mathrm{P}=\ldots ; W_{2 n}-\mathrm{P}=\ldots ; T_{2 n}=\ldots . \ldots V_{2 n}-P=\cdots ; U_{2 n}=\ldots$ ).
9.2 Program written with Maxima software for $2 n=10^{500}$
r:0; n1:10**500 ; for n:5*10**499+10000 thru $5^{*} 10 * * 499+10010$ do
( k:1, a:2*n, c:a-3, test:0, b:prev_prime(a-1),
if primep (a-b)
then print(a-n1,c-n1,b-n1,a-b,b-n1,a-b)
otherwise ( r:r+1,
while test $=0$ do
(if ( primep(c) and primep(a-c))
then ( test:1, print(a-n1,a-n1-3,b-n1,a-b,c-n1,a-c," Ret ",r))
else (test.0, c.c-2*k ))) ),

## 10 Appendix

Application of Algorithm 9:
Table of $U_{2 n}$ and $V_{2 n}$ terms of the Goldbach sequence $\left(G_{2 n}\right)$ computed from program $9.2,\left(2 \leq 2 n \leq 10^{1000}+4020\right)$.
The "** sign" in the table below indicates the results given by the algorithm 9 in case $B$ ) of return to the previous terms of the sequence $\left(G_{2 n}\right)$. WATCH OUT ! For large integers $\mathrm{n}\left(2 \mathrm{n}>10^{9}\right)$, to simplify the display of large numbers, the results are entered as follows : $2 \mathrm{n}-\mathrm{P},(2 \mathrm{n}-3)-\mathrm{P}, \mathrm{W}_{2 \mathrm{n}}-\mathrm{P}, \mathrm{T}_{2 n}, \mathrm{~V}_{2 n}-\mathrm{P}$ and $\mathrm{U}_{2 n}$ with, $\mathrm{P}=\mathrm{M}, \mathrm{R}, \mathrm{G}, \mathrm{S}$, or T constants defined in (2.3).

## 11 Perspectives and Generalizations

11.1 Other Goldbach sequences $\left(G_{2 n}^{\prime}\right)$ and $\left(G^{\prime \prime}{ }_{2 n}\right)$ independent of $\left(G_{2 n}\right)$ may be studied using the increasing sequences of primes $\left(W^{\prime}{ }_{2 n}\right)$, (see 8.5) and $\left(W^{\prime \prime}{ }_{2 n}\right)$ defined by :

For any integer $\mathrm{n} \geq 3, W^{\prime \prime}{ }_{2 n}=\operatorname{Sup}(\mathrm{p} \in \mathcal{P}: p \leq \mathrm{f}(\mathrm{n})$ ), f being a function defined on the interval $\mathrm{I}=[3 ;+\infty[$ and satisfying the following conditions:
*f is strictly increasing on the interval I,
$* \lim _{x \rightarrow+\infty} f(x)=+\infty ; \mathrm{f}(3)=3$.
$* \forall x \in I, f(x) \leq 2 \mathrm{x}-3$.
For example, one of the following functions defined on I can be selected.
a) f: $x \rightarrow a x+3-3 a ;(a \in \mathbb{R}: 0<a \leq 2)$.
b) $\mathrm{g}: \mathrm{x} \rightarrow[4 \sqrt{(3 x)}-9]$ ( $[\mathrm{x}]$ being the integer part of the real number x$)$.
c) $\mathrm{h}: x \rightarrow 6 \ln (\mathrm{x} / 3)+3$.
11.2 Using this method, it would be interesting to study the Schnirelmann density [28] of certain primes such as $3,5,7,11, \ldots . . \ldots$ in the sequence $\left(U_{2 n}\right)$ for $\mathrm{n} \in\left[K_{N} ; P_{N}\right]$ as a function of N .
11.3 It is possible to exceed the values shown in the table ( $2 \mathrm{n}=10^{1000}$ ) by optimizing this algorithm, using supercomputers and more efficients software as Maple .
11.4 Diophantine equations and conjectures of the same nature (Lagrange-Lemoine-Levy conjecture [9], [17], [19],[21],[22], [30]) can be treated using similar reasoning and algorithms.

1) To validate the Lagrange-Lemoine-Levy conjecture, we can study
the following sequences of primes $\left(W L_{2 n}\right),\left(V L_{2 n}\right)$ and $\left(U L_{2 n}\right)$ defined by :
For any integer $n \geq 3, W L_{2 n}=\operatorname{Sup}(\mathrm{p} \in \mathcal{P}: p \leq n-1)$,
a) If $T L_{2 n}=\left(2 \mathrm{n}+1-2 W L_{2 n}\right)$ is a prime, then let:

$$
V L_{2 n}=W L_{2 n} \quad \text { and } \quad U L_{2 n}=T L_{2 n}
$$

b) If $T L_{2 n}$ is a composite number, then there exists an integer $\mathrm{k},(1 \leq k \leq n-3)$ such hat : $U L_{2(n-k)}+2 \mathrm{k}$ is a prime ; then let :

$$
V L_{2 n}=V L_{2(n-k)} \text { and } U L_{2 n}=U L_{2(n-k)}+2 \mathrm{k} .
$$

2) Using the same type of reasoning, a generalized Bezout-Goldbach conjecture of the following form can be validated :
a) Let $K$ and $Q$ be two odd integers, prime to each other : for any integer $n$ such that: $(2 \mathrm{n} \geq 3(\mathrm{~K}+\mathrm{Q}))$, there exist two primes $U^{\prime \prime \prime}{ }_{2 n}$ and $V^{\prime \prime \prime}{ }_{2 n}$ verifying :

$$
\mathrm{K} \cdot U^{\prime \prime \prime}{ }_{2 n}+\mathrm{Q} \cdot V^{\prime \prime \prime}{ }_{2 n}=2 \mathrm{n} .
$$

b) Let $K$ and $Q$ be two integers of different parity, prime to each other : for any integer $n$ such that : $(2 n \geq 3(K+Q)$ ), there are two primes $U^{\prime \prime \prime}{ }_{2 n}$ and $V^{\prime \prime \prime}{ }_{2 n}$ verifying:

$$
\mathrm{K} \cdot U^{\prime \prime \prime}{ }_{2 n}+\mathrm{Q} \cdot \mathrm{~V}^{\prime \prime \prime}{ }_{2 n}=2 \mathrm{n}+1 .
$$

## 12 Conclusion

12.1 An unique recurrent and explicit Goldbach sequence $\left(G_{2 n}\right)=\left(U_{2 n} ; V_{2 n}\right)$, verifying : $\left(\forall \mathrm{n} \in \mathbb{N}+2, U_{2 n}\right.$ and $V_{2 n}$ are primes : $U_{2 n}+V_{2 n}=2 \mathrm{n}$ ), has been developed using an simple and efficient "local" algorithm.
12.2 Silva's [29] record is broken on a personal computer, and it is possible to reach values of the order of $2 \mathrm{n}=10^{1000}$ with a reasonable computation time (less than three hours for the evaluation of ten terms $U_{2 n}$ and $V_{2 n}$ ).
12.3 For a given integer $\mathrm{n} \geq 49$, the evaluation of the terms $U_{2 n}$ and $V_{2 n}$ does not require the computing of all previous terms $U_{2 k}$ and $V_{2 k},(1 \leq \mathrm{k}<\mathrm{n}-1)$. we just need to know the primes $p_{l}, V_{2 r}$ such that :
(12.3.1) $\quad p_{l} \leq 7(\ln (2 n))^{1.3}$ and $2 n-7(\ln (2 n))^{1.3} \leq V_{2 r} \leq 2 n \quad$ (on average).

This property allows quick computing of $U_{2 n}$ and $V_{2 n}$ even for values of 2 n of the order of $10^{1000}$.
12.4 Therefore, the strong Euler-Goldbach and the Lagrange-Lemoine-Levy conjectures are true.
